(54) Title: **WIDEBAND WIRELESS BASESTATION MAKING USE OF TIME DIVISION MULTIPLE-ACCESS BUS TO EFFECT SWITCHABLE CONNECTIONS TO MODULATOR/DEMODULATOR RESOURCES**

(57) Abstract

A wireless communication system basestation making use of a wideband, multichannel digital transceiver having incorporated therein a time division multiple-access (TDM) bus for providing digital samples of a plurality of wireless communication channels, wherein the TDM bus is used as a crossbar switch to permit dynamic allocation of modulator and demodulator signal processing resources. The invention allows various air interface standards, even those having different channel bandwidths, to be serviced by the same basestation, with automatic redistribution of signal processing resources, eliminating the need to reconfigure the basestation when the loading of different types of wireless signaling traffic changes.

**WIDEBAND WIRELESS BASESTATION MAKING USE OF TIME DIVISION
MULTIPLE-ACCESS BUS TO EFFECT SWITCHABLE CONNECTIONS TO
MODULATOR/DEMODULATOR RESOURCES**

FIELD OF THE INVENTION

This invention relates generally to communication networks, and in particular to a wireless communication system basestation making use of a wideband, multichannel digital transceiver having incorporated therein a time division multiple-access (TDM) bus for providing digital samples of a plurality of wireless communication channels, wherein the TDM bus is used as a cross-bar switch to permit dynamic allocation of modulator and demodulator signal processing resources.

BACKGROUND

The basestations used by the providers of current day multiple channel wireless communication services, such as cellular mobile telephone (CMT) and personal communication systems (PCS), typically designate signal processing equipment for each single receiver channel. This is probably a result of the fact that each basestation is configured to provide communication capability for only a limited predetermined number of channels in the overall frequency spectrum that is available to the service provider.

A typical basestation may thus contain several racks of equipment which house multiple sets of receiver and transmitter signal processing components that service a prescribed subset of the available channels. For example, in an Advanced Mobile Phone Service (AMPS) cellular system, a typical basestation may service a pre-selected number of channels, such as 48, of the total number, such as 416, of the channels available to the service provider.

-2-

5 Certain types of wireless service providers would prefer, however, to employ equipment that would be more flexible, both in terms of where it can be located, as well as in the extent of the available bandwidth coverage provided by a particular transceiver site. This is particularly true in rural areas where cellular coverage may be concentrated along a highway, and for which the limited capacity of a conventional 48 channel transceiver may be inadequate. This may also be true in other instances, where relatively large, secure, and protective structures for multiple racks of equipment are not necessarily 10 available or cost effective, such as for PCS applications.

15 One way to resolve this difficulty is to implement a basestation transceiver using a high speed analog-to-digital (A/D) converter and equipment which makes use of efficient digital filtering algorithms such as the Fast Fourier Transform (FFT), to separate the incoming signal energy into multiple ones of the desired channels. On the transmit side, this basestation implementation includes an inverse FFT processing combiner which outputs a combined signal representative of the 20 contents of the communication channel signals processed thereby. In this manner, relatively compact, lightweight, inexpensive, and reliable digital integrated circuits may be used to cover the entire channel capacity offered by the service provider, rather than only the subset of the available 25 channels. For a more detailed description of such a system, please refer to our co-pending United States patent application entitled "Transceiver Apparatus Employing Wideband FFT Channelizer with Output Sample Timing Adjustment and Inverse FFT Combiner for a Multichannel Communication Network" filed April 8, 1994 and which is assigned to Overture Systems, Inc., 30 the assignee of this application.

35 Thus unlike prior art basestations, the wideband digital basestation is capable of receiving any channel. While this provides a certain number of advantages as described above, it also poses a number of unique problems to the service provider.

Perhaps most importantly, there exists a need to efficiently support a varying number of active channels and the

-3-

required connections into the public switched telephone network.

These connections should be made in such a way as to simplify call control. Indeed, it would be desirable for as many of the call set up control functions required by such a basestation were handled to the maximum extent possible by the basestation itself.

By so simplifying the network interface, the Mobile Telephone Switching Office (MTSO) and/or Mobile Switching Center (MSC) through which the basestation is connected to the Public Switched Telephone Network (PSTN) may be freed, as much as possible, from the details of maintaining a proper connection from the PSTN to the remote subscriber unit.

Secondly, the basestation should make efficient use of the available resources to process each call. In particular, while the wideband channelizer separates the signals into channels, certain other signal processing resources such as demodulators and modulators are also required.

Using the wideband front end, any channel in the bandwidth available to the service provider is available at any time. However, it is desirable for such a basestation to only activate as many of the other, per-channel resources as is required to support the present call density.

By making the basestation's implementation of call processing resources as modular as possible, the basestation could initially be configured to support a limited number of channels. Then, as the demand for services grows, additional channels could be supported by the addition of the necessary resources.

In other instances, the basestation should be reconfigurable in the event of an interruption or expansion in one type of service. For example, given the emergence of several air interface standards such as code division multiple access (CDMA) as well as time division multiple access (TDMA) standards for cellular, it is desirable for a given wideband basestation to be able to support each such standard, thereby

-4-

reducing the number of such basestations that need to be deployed. However, it would be desirable if the resources allocated to one particular air interface, when no longer needed, could then be made available to process signals formatted using the other air interface. That is, as the demands of one type of service or the other come and go, the basestation should be automatically reconfigured.

Thus, several difficulties exist with a wideband digital basestation that can process at any time, any one of many channels in the RF bandwidth available to a service provider.

SUMMARY OF THE INVENTION

Briefly, the invention is a wideband transceiver basestation for a wireless communication system. The receiver portion of the basestation includes a digital channelizer which provides digital samples of multiple wireless channel signals, and a time division multiplexed (TDM) data bus to provide switching functionality between the various channel outputs and other basestation receiver resources such as digital demodulators.

On the transmitter side, basestation signal processing resources such as digital modulators are also connected to a multichannel digital combiner over the TDM bus. Thus, the same flexibility in switching functionality is provided between transmitter signal processing resources and the transmitter channel inputs.

More particularly, the wideband basestation transceiver includes a receive antenna and one or more digital tuners that provide wideband digital signal energy to a digital channelizer. The digital channelizer, in turn, produces a plurality of channel signals, with each channel signal representing the signal energy in one of the radio frequency channels. The channel signals each consist of a series of digital samples.

The digital samples of each channel signal are, in turn, connected to a time division multiplex (TDM) bus. A

-5-

basestation controller grants access to the TDM bus by each channel signal in a predetermined timeslot, in a predetermined order.

5 The samples of the digital channel signals are then forwarded to an available one of the associated receiver resources, such as a demodulator. The demodulators, typically implemented in a digital signal processor (DSP), are then connected to an outgoing landline such as a T1 line to a telephone switching office (MTSO) or mobile switching center 10 (MSC) for further connection into the PSTN.

As a result of the switching functionality provided by the TDM bus, the basestation controller is thus capable of assigning receiver resources dynamically, to any channel, at the time the channel becomes active.

15 The invention provides other advantages as well.

For example, the invention allows various air interface standards, even those having different channel bandwidths, to be serviced by the same basestation. For example, the basestation may efficiently service both code division multiple access (CDMA) and time division multiple access (TDMA) signals at the same time. In such an arrangement, there are at least two digital channelizers, with one allocated to separating the incoming RF energy into the channel bandwidths required by TDMA, and another channelizer dedicated to separating the energy into the bandwidth required by CDMA. As the channels are activated, they are then serviced by the pool of demodulator resources, by allocating the correct number of additional time slots to accommodate each standard.

30 If, for example, a wideband CDMA mobile unit goes off line, the timeslots as modulators and demodulators freed thereby can be allocated to processing TDMA signals. This results in automatic on-demand redistribution of basestation resources to one signaling standard or another, without intervention by an MTSO, MSC, or the service provider in any 35 way..

Such a system architecture also exhibits scalability, in the sense that additional DSP processors may be added to

-6-

support additional channels as traffic increases, without having to change the RF front configuration. This is unlike the prior art, where each basestation had a fixed channel allocation, and, to add capacity, one must add additional narrowband receivers and transmitters.

BRIEF DESCRIPTION OF THE DRAWINGS

For a fuller understanding of the advantages provided by the invention, reference should be had to the following detailed description together with the accompanying drawings, in which:

Fig. 4 is a detailed diagram of an addressable bus driver using a first-in, first-out (FIFO) memory;

Fig. 5 is a detailed diagram of an addressable bus receiver using a FIFO;

Fig. 6 is a detailed diagram of an addressable bus transmitter using a FIFO;

Fig. 7 is a sequence of operations performed by a basestation control processor in setting up a connection; and

Fig. 8 is an alternate embodiment of the invention making use of multiple tuners and channelizers to support multiple air interface standards while making maximum use of basestation resources.

DETAILED DESCRIPTION OF A PREFERRED EMBODIMENT

Fig. 1 is a block diagram of a wideband wireless digital basestation 10 according to the invention. Briefly, the basestation 10 consists of a receive antenna 11, one or more

-7-

wideband digital tuners 12, one or more digital channelizers 14, a time division multiplex (TDM) bus 16, a control bus 17, a plurality of digital signal processors (DSPs), a first subset of which are programmed to operate as demodulators 18-1-1, 18-1-2, . . . , 18-1-P (collectively, demodulators 18-1); a second subset of which are programmed to operate as modulators 18-2-1, 18-2-2, . . . , 18-2-Q; and a third subset 18-u of which are presently idle, transport signal (T-1) encoder 20, a T-1 decoder 22, one or more digital combiners 24, one or more wideband digital excitors 26, a power amplifier 28, a transmit antenna 29, a basestation control processor (controller) 30, and a TDM synchronization clock generator 32.

More particularly, the basestation exchanges radio frequency (RF) signals with a number of mobile subscriber terminals (mobiles) 40a, 40b. The RF carrier signals are modulated with voice and/or data (channel) signals which are to be coupled to the public switched telephone network (PSTN) by the basestation 10. The particular modulation in used may be any one of a number of different wireless (air interface) standards such as the well known Advanced Mobile Phone Service (AMPS), time division multiple access (TDMA) such as IS-54B, code division multiple access (CDMA) such as IS-95, frequency hopping standards such as the European Groupe Speciale Mobile (GSM), personal communication network (PCN) standards, and the like. Indeed, in a manner that will be described below, the basestation 10 may even be configured to simultaneously process RF signals formatted according to more than one such air interface at the same time.

On the receive side (that is, with respect to the basestation 10), RF modulated signals are first received at the receive antenna 11, and forwarded to the wideband digital tuner 12. The digital tuner 12 downconverts the RF signal received at the antenna to a intermediate frequency (IF) and then performs an analog to digital (A/D) conversion to produce a digital composite signal 13.

Digital tuner 12 is wideband in the sense that it covers a substantial portion of the bandwidth available to the wireless

-8-

service provider who is operating the basestation 10. For example, if the air interface implemented by the basestation 10 is IS-54B, the wideband digital tuner may downconvert as much as a 12.5 MegaHertz (MHz) bandwidth in the 800-900 MHz range which contains as many as 416 receive and transmit channel signals, each having an approximately 30 kiloHertz (kHz) bandwidth.

The digital channelizer 14 implements a channel bank to separate the downconverted composite digital signal 13 to a plurality, N , of digital channel signals 15.

This digital sampled signal is then further filtered to separate it into the individual 30 kHz channel signals. The digital channelizer 14 can thus be considered as a bank of digital filters with each filter having a 30 kHz bandwidth. The digital channelizer 14 may implement the filter bank using any of several different filter structures, and no particular digital filter structure is critical to the operation of the invention.

However, our co-pending United States patent application entitled "Transceiver Apparatus Employing Wideband FFT Channelizer with Output Sample Timing Adjustment and Inverse FFT Combiner for a Multichannel Communication Network" filed April 8, 1994 and which is assigned to Overture Systems, Inc. the assignee of this application describes several particular embodiments of the digital tuner 12 and digital channelizer 14 in detail.

In any event, the channelizer 14 provides N individual digital channel signals 15, wherein each of the N outputs represent information in one of the radio frequency channels originated by the mobile 40. Usually, one-half of the channels are used for transmitting signals and one-half for receiving signals. Thus, in the IS-54B example being described, N is 208, and thus there are 208 receive and 208 transmit channels implemented by the basestation 10.

These N digital channel signals are then provided over the time division multiplex (TDM) bus 16 to a plurality of digital

-9-

signal processors (DSPs) 18-1-1, 18-1-2, ..., 18-1-P (collectively, demodulator-DSP 18-1). In a manner that will be understood in greater detail shortly, the TDM bus 16 operates as a time division multiplexed cross-bar switch. That is, any one of the N digital channel signals 15 may be connected to any one of the demodulator DSPs 18-1 via the TDM bus 16.

The DSPs 18-1 are each programmed to remove the modulation on each channel signal 15 specified by the air interface standard. There typically is not a one-to-one correspondence between the number of DSPs 18-1 and the number of channel signals, N, provided by the channelizer 14. For example, the DSPs may each process a number, such as 24, of digital channel signals 15 at the same time.

The basestation controller 30, using the VME bus and TDM synchronization clock generator 32, manages access by individual digital channel signals 15 to the TDM bus 16, in a manner that will be described shortly.

The outputs of the digital signal processors 18-1, representing demodulated audio or data signals, are then forwarded over the VME bus 17 to the encoder 20. The VME bus 17 is a well known industry standard relatively high frequency bus for interconnecting digital processors and components.

The encoder 20, in turn, reformats the demodulated signals as necessary for transmission to a local Mobile Telephone Switching Office (MTSO). The demodulated signals may be reformatted according to any one of a number of well-known time multiplex telephone signal transport protocols, such as the so-called T1 span (or E1). The T1 signals are then processed by the MTSO in an known fashion, to ultimately complete a telephone call from the subscriber unit 40 to a desired destination, such as another telephone subscriber who is connected to the Public Switched Telephone Network (PSTN).

Since each T1 span has a limited capacity, there may be more than one T1 signal necessary to accommodate all of the channels serviced by the basestation 10. In the example being

-10-

discussed, each T1 signal may be formatted to carry up to 96 IS-54B bandwidth-compress signals to the MTSO, assuming that the demodulated signals remain as compressed audio. Thus, as few as five T1 lines can be used to carry all of the 416 transmit and receive channels. When not all of the channels are busy, however, on as many of the T1 line resources as are necessary are connected to the MTSO, in a manner that will be understood shortly.

In other words, the demodulated signals output by the DSPs 18-1 may each be sub-rate (e.g., sub-DS0 frequency signals) which still contain additional encoding other than the air interface standard, such as impressed by a bandwidth compression scheme, which is not removed by the basestation 10. Rather, to minimize the required number of time slots used by the T1 signals, such compression may be removed at the MTSO.

The signal flow on the transmit side of the basestation 10 is analogous. Signals are received from the MTSO and provided to the T1 decoder 22, which removes the T1 formatting.

The unformatted T1 signals are then coupled to the DSPs 18 over the bus 17. A subset of the DSPs 18-2-1, 18-2-2, ..., 18-2-Q (collectively, modulators 18-2) then modulate these signals and presents them to the TDM bus 16. Ultimately, these are then each coupled to one of the N digital channel signals 23 input to the combiner 24. As was true in the receive direction, being a cross-bar switch, the TDM bus 16 permits any one of the modulator DSPs 18-2 to be connected to any one of the channel signal inputs 23.

Although each modulator DSP 18-2 typically processes multiple channel signals, each such channel signal generated by the modulator DSP 18-2 is typically assigned one or more unique time slots on the TDM bus 16, with no two channel signals thus occupying the same time slot. Similarly, no two channel signals on the receive side ever occupy the same timeslot on the TDM bus 16.

Other DSPs 18-u may be unused at a particular point in time. However, these unused DSPs remain as an available

-11-

resource to the basestation 10, should a new mobile 40 request access. The manner in which DSPs are allocated at the time of setting up a call will be described in detail below.

5 The digital combiner 24 combines the TDM bus outputs to produce a composite IF digital signal 25 representing the N channels to be transmitted. The digital combiner 24 then feeds this combined signal to a digital exciter 26, which generates an RF signal 27. This RF signal 27 is then amplified by the power amplifier 28 and fed to the transmit antenna 29.

10 A more detailed description of the digital combiner 24 and wideband digital exciter 26 is contained in the above-mentioned co-pending patent application.

15 In order to set up each call, the basestation control processor 32 must exchange certain control information with the MTSO. For example, when a mobile unit 40 wishes to place a call, the mobile unit 40 indicates this by transmitting on one or more control signal channels. These control signals may be exchanged in one of several ways. As shown, the control signals may be in-band or out of band signals present in one or 20 more of the channel signals output by the channelizer 14 or input to the combiner 24. Alternatively, a separate control signal transceiver 35 may be used to receive and transmit such control signaling.

25 In either event, the basestation 10 forwards the request for access by the mobile 40 to the MTSO, to set up the end to end connection. Upon receiving an indication from the MTSO that the connection can be made at the remote end, the basestation 10 then performs a number of steps, to insure that the appropriate data path through the TDM bus is then enabled 30 to support communication with between the newly enabled mobile 40 and the MTSO.

35 For example, the MTSO typically returns a pair of T1 span line and T1 time slot identifiers. These inform the basestation controller 30 on which outgoing T1 line and time slot to place the received signal, and on which incoming T1 line and time slot it can expect to obtain the transmit signal for the mobile 40.

-12-

5 However, before proceeding with a detailed explanation of this call set-up process, a bit more detail of the operation of the TDM bus 16 will be provided. As shown in Fig. 2, the digital channelizer 14 consists of a convolutional digital filter 140, a fast Fourier transform (FFT) 142, as well as a TDM dual port (DP) driver 144.

10 The operation of the convolutional filter 140 and FFT 142 is not critical to the present invention, and is explained in the co-pending application. It is sufficient here to say that the convolutional filter 140 and FFT 142 make use of multirate digital signal processing techniques, such as overlap and add or polyphase, to efficiently implement a digital filter bank by 15 (1) grouping samples of the downconverted signal 13 together and multiplying them by a weighting function, and then (2) forwarding them to the FFT 142 for conversion into the N individual channel signals.

20 An exemplary DSP demodulator 18-1-1 and modulator 18-2-1 are also shown in Fig. 2. The demodulator DSP 18-1-1 includes a TDM first-in first-out (FIFO) driver 180-1, a TDM FIFO receiver 182-1, a DSP central processing unit 184-1 and program memory 186-1. Similarly, the modulator DSP 18-2-1 includes a TDM FIFO driver 180-2, a TDM FIFO receiver 182-2, a DSP central processing unit 184-2 and program memory 186-2.

25 Indeed, the modulator and demodulator DSPs may share the same hardware architecture, with the only difference being the in the program which is enable in the program memory 186, which in turn may control whether the TDM receiver or TDM driver hardware is enabled.

30 Thus, in the DSP demodulator 18-1-1, only the TDM receiver 182-1 is enabled (as indicated by the dashed lines around the driver 180-1), since the demodulator 18-1-1 only receives data from the TDM bus 16. Likewise, only the TDM driver 180-2 is enabled in the DSP modulator 18-2-1, since it only transmits data on the TDM bus 16.

35 On the transmit side, the digital combiner 24 consists of a TDM dual port (DP) receiver 244, an inverse FFT 242, and

-13-

deconvolutional digital filter 240. In a manner that is described below, the TDM DP receiver 244 reads each of the data samples off the TDM bus 16 in their assigned time slot, and provides them to the inverse FFT 242 in the required order.

5 The samples are then operated on by the inverse FFT 242 and deconvolutional filter 240, to provide the composite digital signal 25 (Fig. 1). Again, further details of the operation of the inverse FFT 242 and deconvolutional filter 240 are not necessary here, and they are discussed in the co-
10 pending patent application should the reader be interested.

Returning attention now to the channelizer 14, a detailed diagram of the TDM DP driver 144 is shown in Fig. 3. Briefly, it operates to assert the output samples from the FFT 142 in the proper time slots on the TDM bus 16. In order to simplify the implementation of the TDM bus 16, these time slots are fixedly assigned to particular channels (such as in ascending order by frequency and time slot number). Thus, a sample of a given one, k , of the N channel signals, will always appear in a particular time slot, k , when it is active.

20 The DP driver 144 consists of a TDM slot counter 200, a first Dual Port Random Access Memory (DP-RAM) referred to as the enable DP-RAM 202, a second DP-RAM referred to as the data DP-RAM 204, and a driver 208 having an enable input EN.

25 As is conventional, each of the DP-RAMs have two separate address and data ports for reading and writing data, namely, input address and data ports AI and DI, and output address and data ports AO and DO.

30 In operation, the TDM slot counter 200 receives a pair of signals generated by the TDM synchronization circuit 32 (Fig. 1). The first signal, TDM CLK, is a digital clock signal identifying the clock periods, or time slots, on the TDM bus 16. The second signal is a TDM FRAME SYNC signal, indicating when a new frame starts on the TDM bus 16.

35 The TDM slot counter 200, which is a standard digital counter, receives the TDM FRAME SYNC signal at a reset input R, and the TDM CLK signal at a clock input (denoted by a chevron

-14-

in the Figures). Thus, the TDM slot counter 200 continuously keeps track of which consecutively numbered slot on the TDM bus 16 is presently active.

5 The enable RAM 202 generates an enable signal 203 indicating when the TDM DP driver 144 may assert data on the TDM bus 16. The AI and DI inputs to the enable DP-RAM 202 are typically written into by the basestation controller 30 during the process of setting up a new call. In particular, as shown in the table depicting the contents of the enable DP-RAM 202, a 10 location in the RAM is associated with each time slot on the TDM bus 16 (e.g., if the TDM bus contained 512 time slots, then the RAM 202 has 512 locations).

15 A logical "0" in the associated enable DP-RAM 202 location indicates that the TDM driver is inactive in the time slot, that is, no data is to be asserted at that time. A logical "1" in the associated location indicates that the time slot has been assigned to this particular TDM driver 144.

20 Thus, to enable a connection through the TDM bus 16, one step for the basestation controller 30, via the VME bus 17, is to write a logical "1" into the DP-RAM 202 location "x" associated with the newly enabled digital channel signal "x". In the example, shown, a "1" has been written at locations "27" and "30", indicating that this particular TDM driver 144 is now active in timeslot numbers 27 and 30.

25 The data DP-RAM 204 acts as a buffer, writing the digital channel signal samples output by the FFT at the DI input of the data DP-RAM 204. The DP-RAM 204 then stores the data samples until addressed by the TDM slot counter at the output side.

30 A data dual port (DP) RAM 204 is as a buffer in the case of processing the FFT output. This is because although the samples do come in bursts, or frames, the samples are not necessarily provided by the FFT 142 in the same order as they must be output onto the TDM bus 16. This is a particular phenomenon of at least one of the channelizer algorithms used. Thus, an address associated with each output sample from the 35 FFT is used to determine at which location each sample is written in the data DP-RAM 204.

-15-

However, the input data is already in the correct order for the TDM FIFO driver 180-2 used by the DSP modulator. Such a TDM driver 180-2 can thus use a first-in first out memory (FIFO) 210 in the place of a data DP-RAM. As shown in Fig. 4, the configuration and operation of such as TDM FIFO driver 180-2 is somewhat similar to the DP driver 144.

In particular, the TDM slot counter 200, enable DP-RAM 202 and driver 208 operate in the same way as for the embodiment of Fig. 3. The only difference is in the connection of the clock signals to the FIFO 210. On the input side, a clock signal is provided by the data source (e.g., the DSP processor 184-2) to cause data to be stored in the FIFO. The signal from the enable DP-RAM 202 is used to clock the FIFO output, DO.

A detailed diagram of the TDM FIFO receiver 182-1 is shown in Fig. 5. It includes a TDM slot counter 200, enable DP-RAM 202, bus receiver 212, and FIFO 214. The TDM slot counter 200 and enable DP-RAM 202 operate as for the TDM FIFO driver 180-1 shown in Fig. 4, to identify when the receiver 212 is to be active. The FIFO 214 is connected to the output of the receiver 212, having its input port connected to the enable DP-RAM 202 output. The output side of the FIFO is clocked as needed by the destination for the data (such as the DSP processor 184-1 in Fig. 2).

The TDM DP receiver 244 is shown in detail in Fig. 6. As for each of the other driver/receivers, it includes a TDM slot counter 200, enable DP-RAM 202. It includes a data DP-RAM 220 operating similarly to the data DP-RAM in the TDM DP driver 144 (Fig. 3) and bus receiver 218.

With this background in mind, the details of how the basestation control processor 30 effects the switching operation of the TDM bus 16 can now be better understood.

Fig. 7 is a flowchart of these operations. This sequence of steps is initiated (step 300) when the basestation controller 30 receives control signals from the mobile 40 (Fig. 1) indicating that the mobile wishes to have access to the PSTN. The controller 30 then determines whether a free

-16-

transmit and receive frequency (step 302) are available among the N channels.

An available modulator DSP and demodulator DSP resource are then identified (step 303) by examining a list 33 of free DSP resources maintained in a memory portion 31 of the basestation controller 30 (Fig. 1). The list 33 is updated by removing the two DSPs once allocated.

Access to an MTSO T1 channel (e.g., access to one or more T1 time slots as needed on a particular T1 span line) is then requested from the MTSO by issuing the appropriate MTSO control signaling (step 304). The MTSO then returns T1 span and time slot identifiers to be used for the transmit and receive channels for this connection.

In the next step (306), the appropriate destination and source information is written into the various TDM bus drivers and receivers.

In particular, given a receive channel identification, a receive channel signal time slot on the TDM bus is thus identified. The corresponding location of the enable DP-RAM 202 in the TDM DP driver 144 associated with this time slot is then set to a logical "1" in the manner already described.

Next, a logical "1" is also written into the enable DP-RAM in the TDM receiver 182-1 associated with the DSP demodulator 18-1 which was identified as being an available resource. If the per-channel bandwidth is greater than that which can be supported by a single timeslot, then a sufficient number of logical "1"s are written into the appropriate locations.

Also, now given a transmit channel identification, the free DSP modulator 18-2 is enabled (step 306) to use the TDM bus 16, by writing a logical "1" into the enable DP-RAM of the TDM driver 180-2 connected to the available one of the DSP modulators 18-2. To complete the connection, a logical "1" is also written into the location of the TDM DP receiver 244 associated with the identified transmit channel.

Finally (step 308), the basestation controller 30 issues control signals to the mobile 40 and MTSO to indicate that the connection has been set up.

-17-

The invention can also be used to advantage in implementing a basestation 10 which simultaneously services mobiles 40 which use different air interface standards. That is, the basestation 10 may at the same time process signals from a first mobile 40a which uses TDMA (IS-54B) signaling, as well as a second mobile 40b which uses CDMA signaling (IS-95).

As shown in Fig. 8, to support this implementation, the basestation 10 includes a pair of wideband digital tuners 12-1, 12-2. The first digital tuner 12-1 downconverts a bandwidth, such as 5 MHz, from an RF bandwidth which is occupied by TDMA signals. A second digital tuner section 12-2 downconverts a bandwidth, such as 7.5 MHz, which is occupied by CDMA signals.

Next, the tuners 12-1, 12-2 forward the downconverted signals to respective channelizers 14-1, 14-2. The TDMA channelizer 14-1 is configured to separate the received signal into the 30 kHz bandwidth channels specified by IS-54B. Likewise, the CDMA IS-95 channelizer 14-2 is configured to provide 1.25 MHz channels as specified by that standard.

The modulators and demodulators are then grouped according to the air interface modulation they must deal with. For example, at any given instant in time, a certain number of DSPs 18-1-T will have been allocated to operate as demodulators for the TDMA channels provided by the TDMA channelizer 14-1. A different set of DSP processors 18-1-C will be serving as demodulators for the CDMA channels provided by the CDMA channelizer 14-2. The active modulator DSPs will likewise be so allocated.

Thus, assuming that each of the DSPs 18 can be configured to execute either a TDMA modulation/demodulation program or a CDMA modulation/demodulation program by simply accessing the correct program memory, the available DSP resources are only allocated as needed.

In other words, the DSPs (and associated T1 connections, for that matter) are allocated according to user demand automatically, and without intervention by the service provider. Thus, for example, as more customers migrate to

-18-

using CDMA, additional CDMA channels are automatically made available and processed by the DSPs, at the expense of the unused TDMA channels.

5 A number of advantages can now be seen for a basestation 10 configured according to the invention. By disposing the TDM bus 16 between the output of the wideband digital channelizer 14 and the demodulator DSPs 18-1, the demodulator DSPs 18-1 may be allocable only as needed. Similarly, the modulator DSPs 18-2 are allocable as needed, since the TDM bus 16 is disposed 10 between them and the digital combiner 24 as well.

15 Thus, if the basestation 10 is expected to service only a small number of channels, a correspondingly small number of modulator and demodulator DSPs can be installed in the basestation 10. As the basestation's demands increases, these additional RF channels can be serviced by simply adding more 20 DSPs, and without having to reconfigure the RF front end.

25 Another advantage is provided in that this switching functionality is distributed at the basestation level as much as possible. In particular, unlike certain prior cellular signal switching techniques, the MTSO need not be concerned with the details of how the mobile units 40 are connected through the basestation. Indeed, the MTSO need not even know or care about which transmit and receive frequencies have been assigned to a particular mobile. All the MTSO need provide is 30 identification of a T1 transport line and time slot on which it expects to receive and provide signals from and to the mobile.

35 Furthermore, because the basestation may efficiently allocate its demodulator/modulator resources, a number of different air interface standards may be supported by the basestation at the same time, without the need to determine in advance an exact plan for allocating receiver/transmitter resources for each air interface type. Upon detecting a request by a new mobile for access, the basestation simply determines the type of air interface used by the mobile, and then signals the appropriately programmed DSPs, or even initiates the DSPs to run a different modulator/demodulator program, as required to support the additional mobile.

-19-

While we have shown and described several embodiments in accordance with the present invention, it is to be understood that the invention is not limited thereto, but is susceptible to numerous changes and modifications as known to a person skilled in the art, and we therefore do not wish to be limited to the details shown and described herein but intend to cover all such changes and modifications as are obvious to one of ordinary skill in the art.

-20-

CLAIMS

1. A basestation for processing signals in a multiple mobile subscriber unit wireless communication system comprising:

an antenna for receiving signals from a plurality of the mobile units as a composite radio frequency (RF) signal;

wideband digital tuner means, connected to the antenna, for downconverting a selected bandwidth of the RF signal to an intermediate frequency (IF), and for performing an analog to digital conversion on the IF signal, to provide a wideband digital tuner output signal;

digital channelization means, being connected to receive the wideband tuner output signal, and providing multiple digital channel signal outputs, each digital channel signal output having a predetermined channel bandwidth, and each digital channel signal corresponding to one of the signals received from one of the mobile units;

a plurality of digital signal processing means, for providing digitally processed channel signal outputs; and

time division multiplex switching means, disposed between the multiple digital channel signal outputs and the plurality of digital signal processing means, the switching means for interconnecting any one of the multiple digital channel signal outputs to any one of the plurality of digital signal processing means.

2. The basestation of claim 1 wherein the signals received from the mobile units contain air interface modulation, and the digital signal processors include demodulators to remove the air interface modulation.

3. The basestation of claim 1 additionally comprising: signal-transport encoding means, connected to the output of the digital signal processing means, for encoding the digitally processed channel outputs for further transmission to a mobile telephone switching office (MTSO).

-21-

4. The basestation of claim 3 wherein the signal-transport encoding means is a T1 encoder.

5. The basestation of claim 1 additionally comprising:
10 second digital channelization means, being connected to receive the wideband tuner output signal, and providing a second set of multiple digital channel signal outputs, each one of the second set of the digital channel signal outputs having a predetermined channel bandwidth which is different from the predetermined channel bandwidth of said above mentioned first digital channel signals, and each one of the second set of digital channel signals corresponding to one of the signals received from one of the mobile units.

15 6. The basestation of claim 1 additionally comprising:
20 second wideband tuner means, connected to the antenna, for downconverting a second selected bandwidth of the RF signal to a second intermediate frequency (IF), and for performing an analog to digital conversion on the second IF signal, to provide a second wideband digital tuner output signal; and
25 second digital channelization means, being connected to receive the second wideband tuner output signal, and providing a second set of multiple digital channel signal outputs, each one of the second set of the digital channel signal outputs having a predetermined channel bandwidth which is different from the predetermined channel bandwidth of said above mentioned first digital channel signals, and each one of the second set of digital channel signals corresponding to one of the signals received from one of the mobile units.

30 35 7. A basestation as in claim 6 wherein the first and second set of digital channel signals are modulated in accordance with first and second air interface standards, respectively.

-22-

8. A basestation as in claim 7 wherein the digital signal processors include a first set of digital signal processor means for demodulating said first set of digital channel signals, and a second set of digital signal processors for demodulating said second set of digital channel signals.

9. A basestation as in claim 7 wherein said first and second air interface standards are each different one of a time division multiplex (TDMA), code division multiplex (CDMA), Advanced Mobile Phone System (AMPS), Personal Communications System (PCS) or Groupe Especiale Mobile (GSM).

10. A basestation as in claim 1 additionally comprising:
15 basestation controller means, connected to the time division multiplex switching means and the digital signal processing means, for maintaining a list of unused digital signal processing means that are not presently interconnected through the time division multiplex switching means to one of the digital channel outputs, and for dynamically allocating digital signal processing means from the list of unused digital signal processing means to be interconnected to one of the digital channel outputs only when the digital channel output contains an active signal being transmitted by the mobile unit which has not yet been assigned to one of the digital signal processing means.

-23-

channel signals, for receiving the TDM bus synchronization signals and the driver address signals, for storing the driver address signals, and for asserting the digital channel signal on the TDM bus when the value of driver address signals corresponds to the value of the bus synchronization signals, thereby indicating that a timeslot associated with the digital channel signal is currently active.

10 12. A basestation as in claim 11 wherein the basestation controller means, connected to the TDM bus, additionally generates receiver address signals, and the time division multiplex switching means additionally includes:

15 TDM bus receiver means, connected to the TDM bus, the basestation controller means, and at least one of the digital signal processor means, for receiving the TDM bus synchronization signals and the receiver address signals, for storing the receiver address signals, and for reading a signal asserted on the TDM bus and providing such asserted signal to the digital signal processor means when the value of receiver address signals corresponds to the value of the bus synchronization signals, indicating that a timeslot associated with the digital signal processor is currently active.

20 25 13. A wideband basestation as in claim 6 wherein the first and second channelizers each comprise:

a convolutional digital filter, connected to receive the respective one of the digitized wideband signals; and

30 35 a fast Fourier transform (FFT) processor, connected to receive the output of the convolutional digital filter, and to provide the digital channel signals.

14. A basestation as in claim 1 additionally comprising: a second plurality of digital signal processing means, connected to receive digital input signals from a communication signal source;

a wideband digital combiner, being connected to receive a second plurality of digital channel signals, and to provide a

-24-

composite digital signal for transmission;

5 wherein the time division multiplex switching means is also disposed between the second plurality of digital signal processors and the wideband digital combiner, the switching means connecting any one of the second set of digital signal processors to any one of the digital channel signals input to the combiner;

10 a wideband digital exciter, connected to receive the composite digital signal and to provide a combined RF signal; and

15 a transmit antenna, connected to receive the combined RF signal and the radiate the combined RF signal.

15. A basestation as in claim 14 additionally comprising:
20 basestation controller means, connected to the time division multiplex switching means and the first and second plurality of digital signal processing means, for maintaining a list of all unused digital signal processing means that are not presently interconnected through the time division multiplex switching means to one of the digital channel outputs, and for dynamically allocating digital signal processing means from the list of unused digital signal processing means to function as one of the first or second digital signal processing means only when the digital channel output contains an active signal being transmitted by the mobile unit which has not yet been assigned to one of the digital signal processing means, or when the digital inputs from the communications source are active.

30 16. A wideband basestation transceiver including:

a wideband digital tuner that provides a wideband digital signal at an output;

35 a digital channelizer, connected to the wideband tuner, to produce a plurality of sampled channel signals, with each channel signal representing signal energy in one of a plurality of radio frequency channels serviced by the basestation;

a time division multiple-access (TDM) data bus;

-25-

means for selectively connecting the digital samples of each channel signal, in turn, to the TDM bus;

5 basestation controller means, for controlling the means for selectively connecting the digital samples of each channel signal to the TDM bus, by so connecting each channel signal in a predetermined timeslot, in a predetermined order;

10 means, coupled to the TDM bus, for selecting the digital samples in a particular timeslot; and for generating a reconstructed channel signal thereby;

means for allocating a demodulator to be coupled to the reconstructed channel signal when the associated radio frequency channel is active, the demodulator providing a demodulated channel signal;

15 means for allocating a T1 line encoder to the demodulated channel signal, to format the demodulated channel signal for transmission over a T1 span line; and

20 means for coupling the T1 line to a mobile telephone switching office (MTSO) or mobile switching center (MSC) for further connection into the public switched telephone network (PSTN).

INTERNATIONAL SEARCH REPORT

Inte ~~onal~~ Application No
PCT/US 95/01045A. CLASSIFICATION OF SUBJECT MATTER
IPC 6 H04Q7/30 H04B7/26

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
IPC 6 H04Q H04B

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	US,A,5 289 464 (WANG) 22 February 1994 see the whole document ---	1-14, 16
Y	MOBILE RADIO CONFERENCE, 13 November 1991 - 15 November 1991 VALBONNE, FR, pages 161-168, XP 000444231 BEHAGUE ET AL. 'Modularity and Flexibility: The Keys to Base station System Configuration for the GSM Network' see page 161, right column, line 1 - line 23 see page 163, left column, line 8 - right column, line 6 see page 165, right column, line 1 - page 167, left column, line 10; figures 1,2,6 --- -/-	1-10, 13, 14, 16

 Further documents are listed in the continuation of box C. Patent family members are listed in annex.

* Special categories of cited documents :

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

- "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- "&" document member of the same patent family
